Reflection assignment 3

For this assignment I was tasked to mess with the ai models settings we learned in our previous class. We had to first change the model's personality through the developer role, then provide the model with an example of what we should expect for an answer and proceed with the real question/problem to solve. This time around we had to find a way to make the ai calculator give us a wrong answer, which was pretty hard to be honest, kept me wondering how the teacher managed to pull it off so easily. No matter what equation I gave it at first it was still giving me the good answer after so many tries. It wasn't until I cranked the temperature to 2.0 that it started acting differently. Looking at its response it looks like it was on the verge of giving me a good answer, but it started spewing gibberish at me, so I'll take it as a win. Same thing happened on my other attempts. I also noticed that turning up the temperature will also result in a longer waiting time for a response, I assume it's because the ai model doesn't know when to stop itself, so I think it's safe to say that anything past 1.2 is too much.

This assignment made me realize that there is no way we will achieve AGI. At first my stance on AGI wasn't as strong as now; I knew that artificial intelligence was basically just array of words being re-arranged giving the illusion that we're speaking to something smarter and extraordinary, but I'm glad this class is bringing me back down to earth.
